

# Signs and Symptoms of Active **TUBERCULOSIS**

**Tuberculosis (TB) is a potentially serious infectious bacterial disease that mainly affects the lungs.**

The bacteria that cause TB are spread when an infected person coughs or sneezes.

Most people infected with TB don't have symptoms. When symptoms do occur, they usually include coughing (sometimes blood-tinged), weight loss, night sweats, and a fever.

Treatment isn't always required for those without symptoms. Patients with active symptoms will require a course of treatment involving multiple antibiotics.

Coughing that Lasts three or More Weeks

Coughing Up Blood

Chest Pain or Pain with Breathing or Coughing

High Fever
